

PHP Send Mail Form

Figure 1: MailMan

Just a simple **HTML** form:

- an input **email**
- a text area **message**
- a **send** submit button

When you click on the **send** submit button, it obviously send the **message** by mail to the recipient set in the **email** input!

To do that, you have to use a **PHP** Backend, check the official documentation, there is a **function** for that.

Bonus

- Use *Bootstrap* OR *Foundation* OR *Material Design Light*
- Check if the mail address is valid (use **REGEX**)
- Limit the size of the message to 500 characters
- Let user add multiple recipients in **email** input
- Allow emoji, bold text, images, even youtube videos
- Or anything else that you think is a cool feature!
